

Maximizing Performance Monitoring of VMware Environments with Sightline

Sightline offers in depth monitoring of your entire VMware environment. We utilize two different strategies to provide you with the best overall view of your virtual environment. First we look at your vCenter Servers. This provides you with the basic monitoring of everything you have in your virtual space.

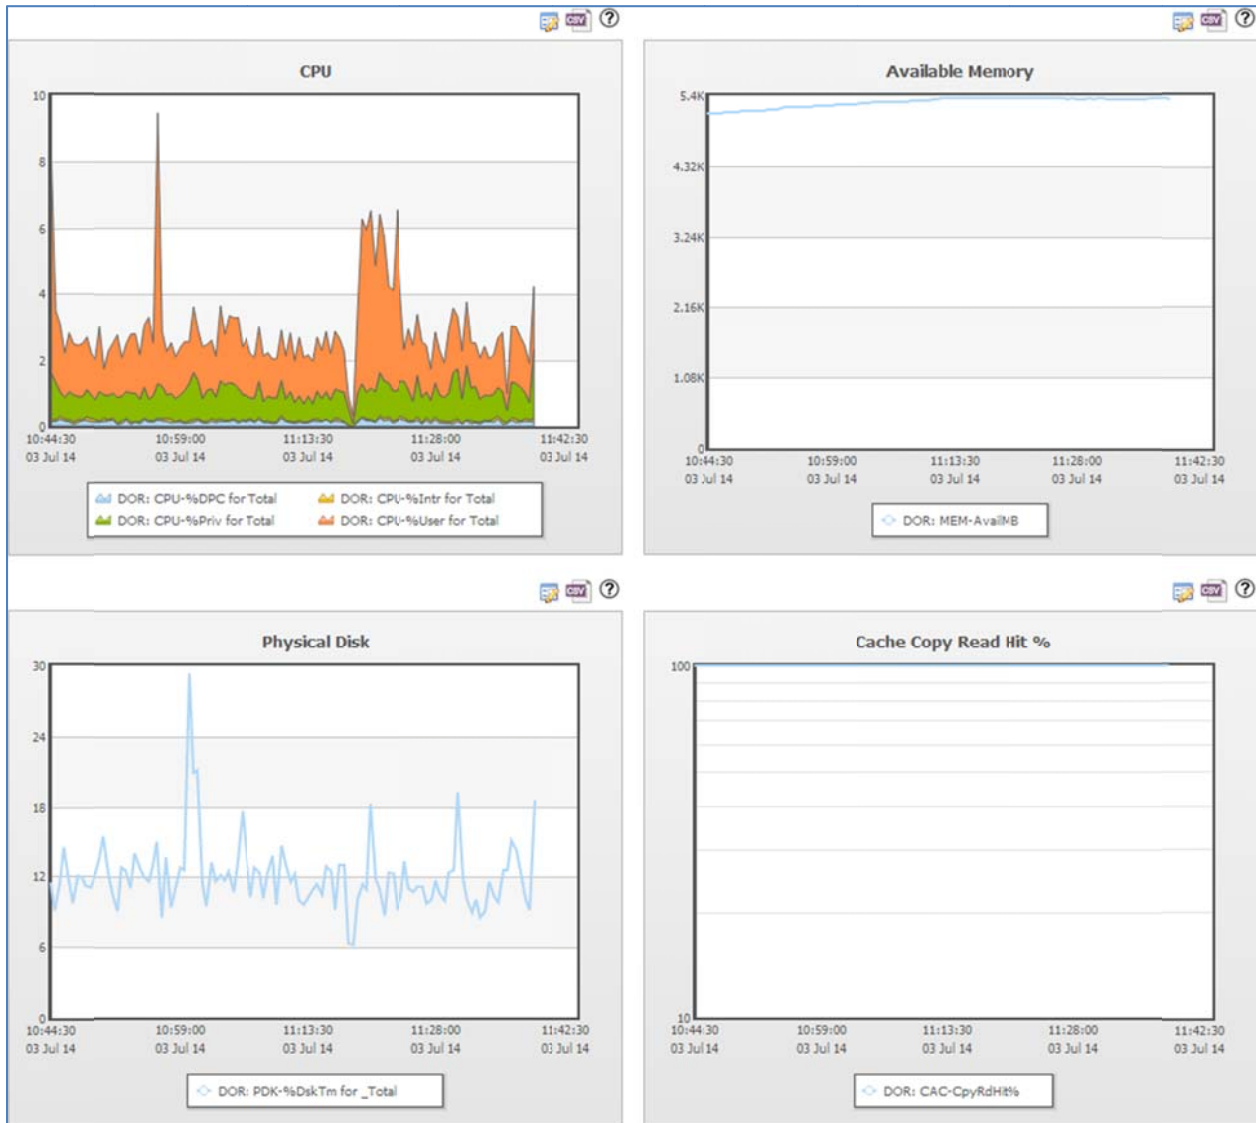

Sightline utilizes the VMware SOAP API to collect these performance counters. Sightline reports on the performance of the host and each configured virtual machine. The Sightline Power Agent for VMware vCenter collects metrics for CPU, System, Memory, Disk, and Network for each of your VMs.

Second, we utilize our Power Agents to provide an in depth view of your mission critical systems and applications. By utilizing the Power Agent on specific systems within your virtual environment, you gain the control to monitor everything and only deploy the Agent where it is absolutely necessary. This gives you the ability to set workloads and use Interface Agents to provide you with low level and process data so you can proactively act to keep these systems and applications performing at the necessary levels.

By utilizing the knowledge base of the Sightline tool you can gain the best of both worlds with our approach to monitoring your virtual environment. You can gain the ability to agentlessly monitor all of your guest systems to gain insight into their performance. And at the same time you can utilize our Power Agents to provide you deep dive analysis and the low level data that Sightline has become known for showing you with our tool on your most mission critical systems and applications. With this approach you can have the largest and most complex virtual environment and still gain the insight you are used to seeing with your current Sightline deployment.

Maximizing Performance Monitoring of VMware Environments with Sightline
